Participants reported the most intense strain in December 2020 and that intensity appears to be slightly decreasing. This decrease may be related to the increase in vaccine distribution.

Methods: REDCap online surveys were distributed to primary care professionals weekly starting May 18, 2020. Participants can choose to complete the survey once or several times.

Participants: As of March 2, 2021, we have recruited 1,010 participants from all 50 states: 39% physicians, 10% nurse practitioners and physician assistants, 15% nurses, 8% medical assistants, 18% behavioral health providers, 5% nonclinical, and 5% other clinical; 78% of participants are women, 89% white, and the average years working in their current role is 10 years (median: 0.1 to 70 years).

Results: 57% of participants are experiencing burnout in one or more domains (see graphic). Nearly all of respondents reported some degree of COVID strain (98%; n = 387). Self-reported COVID strain (scale 1 - no impact to 5 – severe impact) has significantly changed over time.

Note: *Data cleaning has resulted in the removal of potential duplicates, incomplete responses, and ineligible participants (total of 43 removed from analysis to date). Interpret preliminary results with caution. The findings are not generalizable given the small sample size. In other words, we cannot assume these data reflect all primary care professionals. The number of respondents may change based on the questions posed for the week/month. The aMBI (Riley, et al., 2017) was modified to assess acute (weekly) burnout (range of each subscale: 0-12). Scoring: Exhaustion 6+; Depersonalization 3+; Accomplishment <7. Therefore, the results cannot be compared across studies using the aMBI.
